

Edit

# Go cheatsheet

## Introduction

|  |
|--|
| <b>A tour of Go</b><br>(tour.golang.org) |
| <b>Go repl</b><br>(repl.it)              |
| <b>Golang wiki</b><br>(github.com)       |

## Hello world

|   |
|---|
| hello.go  |
| <pre>package main  import "fmt"  func main() {     message := greetMe("world")     fmt.Println(message) }  func greetMe(name string) string {     return "Hello, " + name + "!" }</pre> |
| \$ go build   |
| Or try it out in the <a href="#">Go repl</a> , or <a href="#">A Tour of Go</a> .  |

## Variables

|   |
|---|
| Variable declaration                    |
| <pre>var msg string msg = "Hello"</pre> |
| Shortcut of above (Infers type)         |
| <pre>msg := "Hello"</pre>               |

## Constants

|   |
|---|
| <pre>const Phi = 1.618</pre>                                    |
| Constants can be character, string, boolean, or numeric values. |
| See: <a href="#">Constants</a>                                  |

# # Basic types

## Strings

|                                      |
|--------------------------------------|
| <pre>str := "Hello"</pre>            |
| <pre>str := `Multiline string`</pre> |
| Strings are of type string.          |

## Numbers

|   |
|---|
| Typical types   |
| <pre>num := 3           // int num := 3.          // float64 num := 3 + 4i      // complex128 num := byte('a')  // byte (alias for uint8)</pre> |
| Other types   |

## Arrays

|   |
|---|
| <pre>// var numbers [5]int numbers := [...]int{0, 0, 0, 0, 0}</pre> |
| Arrays have a fixed size.   |

## Slices

Pointers

```
func main () {  
  
    fmt.Println("Value is", b)  
}
```

```
func getPointer () (myPointer *int) {  
    a := 234  
  
}
```

```
a := new(int)
```

Pointers point to a memory location of a variable. Go is fully garbage-collected.

See: [Pointers](#)

```
var u uint = 7           // uint (unsigned)  
var p float32 = 22.7    // 32-bit float
```

Type conversions

```
i := 2  
f := float64(i)  
u := uint(i)
```

See: [Type conversions](#)

```
slice := []int{2, 3, 4}
```

```
slice := []byte("Hello")
```

Slices have a dynamic size, unlike arrays.

# Flow control

Conditional

```
rest()  
  
groan()  
  
work()  
}
```

See: [If](#)

Statements in if

```
    fmt.Println("Uh oh")  
}
```

A condition in an `if` statement can be preceded with a statement before a `;`. Variables declared by the statement are only in scope until the end of the `if`.

See: [If with a short statement](#)

Switch

```
switch day {  
    case "sunday":  
        // cases don't "fall through" by default!  
        fallthrough  
  
    case "saturday":  
        rest()  
  
    default:  
        work()  
}
```

See: [Switch](#)

For loop

```
for count := 0; count <= 10; count++ {  
    fmt.Println("My counter is at", count)  
}
```

For-Range loop

```
entry := []string{"Jack","John","Jones"}  
for i, val := range entry {  
    fmt.Printf("At position %d, the character %s is  
}
```

While loop

See: [For loops](#)

See: [For-Range loops](#)

```
n := 0
x := 42
for n != x {
    n := guess()
}
```

See: [Go's "while"](#)

## # Functions

### Lambdas

```
return x > 10000
}
```

Functions are first class objects.

### Multiple return types

```
a, b := getMessage()
```

```
func getMessage() (a string, b string) {

}
```

### Named return values

```
func split(sum int) (x, y int) {
    x = sum * 4 / 9
    y = sum - x

}
```

By defining the return value names in the signature, a return (no args) will return variables with those names.

See: [Named return values](#)

## # Packages

### Importing

```
import "fmt"
import "math/rand"
```

```
import (
    "fmt"      // gives fmt.Println
    "math/rand" // gives rand.Intn
)
```

Both are the same.

See: [Importing](#)

### Aliases

```
r.Intn()
```

### Packages

```
package hello
```

Every package file has to start with package.

### Exporting names

```
func Hello () {
    ...
}
```

Exported names begin with capital letters.

See: [Exported names](#)

# # Concurrency

## Goroutines

```
func main() {
    // A "channel"

    // Start concurrent routines

    // Read 3 results
    // (Since our goroutines are concurrent,
    // the order isn't guaranteed!)
}
```

```
func push(name string, ch chan string) {
    msg := "Hey, " + name
}
```

Channels are concurrency-safe communication objects, used in goroutines.

See: [Goroutines](#), [Channels](#)

## Buffered channels

```
ch <- 1
ch <- 2
ch <- 3
// fatal error:
// all goroutines are asleep - deadlock!
```

Buffered channels limit the amount of messages it can keep.

See: [Buffered channels](#)

## WaitGroup

```
func main() {

    for _, item := range itemList {
        // Increment WaitGroup Counter

        go doOperation(item)
    }
    // Wait for goroutines to finish

}
```

```
func doOperation(item string) {

    // do operation on item
    // ...
}
```

A WaitGroup waits for a collection of goroutines to finish. The main goroutine calls Add to set the number

## Closing channels

Closes a channel

```
ch <- 1
ch <- 2
ch <- 3
```

Iterates across a channel until its closed

```
...
}
```

Closed if ok == false

```
v, ok := <- ch
```

See: [Range and close](#)

of goroutines to wait for. The goroutine calls `wg.Done()` when it finishes. See: [WaitGroup](#)

# # Error control

## Defer

```
func main() {  
  
    fmt.Println("Working...")  
}
```

Defers running a function until the surrounding function returns. The arguments are evaluated immediately, but the function call is not ran until later.

See: [Defer](#), [panic](#) and [recover](#)

## Deferring functions

```
func main() {  
  
    fmt.Println("Working...")  
}
```

Lambdas are better suited for defer blocks.

```
func main() {  
    var d = int64(0)  
  
    fmt.Print("Done ")  
    d = time.Now().Unix()  
}
```

The defer func uses current value of d, unless we use a pointer to get final value at end of main.

# # Structs

## Defining

## Literals

```
v := Vertex{X: 1, Y: 2}
```

```
// Field names can be omitted  
v := Vertex{1, 2}
```

## Pointers to structs

```
v := &Vertex{1, 2}  
v.X = 2
```

Doing `v.X` is the same as doing `(*v).X`, when `v` is a pointer.

```
func main() {
    v := Vertex{1, 2}
    v.X = 4
    fmt.Println(v.X, v.Y)
}
```

See: [Structs](#)

```
// Y is implicit
v := Vertex{X: 1}
```

You can also put field names.

## # Methods

### Receivers

```
type Vertex struct {
    X, Y float64
}
```

```
return math.Sqrt(v.X * v.X + v.Y * v.Y)
}
```

```
v := Vertex{1, 2}
v.Abs()
```

There are no classes, but you can define functions with receivers.

See: [Methods](#)

### Mutation

```
v.X = v.X * f
v.Y = v.Y * f
}
```

```
v := Vertex{6, 12}
v.Scale(0.5)
// `v` is updated
```

By defining your receiver as a pointer (\*Vertex), you can do mutations.

See: [Pointer receivers](#)

## # Interfaces

### A basic interface

```
type Shape interface {
    Area() float64
    Perimeter() float64
}
```

### Methods

### Struct

```
type Rectangle struct {
    Length, Width float64
}
```

Struct Rectangle implicitly implements interface Shape by implementing all of its methods.

```
func (r Rectangle) Area() float64 {
    return r.Length * r.Width
}

func (r Rectangle) Perimeter() float64 {
    return 2 * (r.Length + r.Width)
}
```

The methods defined in Shape are implemented in Rectangle.

Interface example

```
func main() {
    var r Shape = Rectangle{Length: 3, Width: 4}
    fmt.Printf("Type of r: %T, Area: %v, Perimeter: %v.", r, r.Area(), r.Perim
}
```
